A scenic view of a turquoise beach with people swimming and boats in the distance. The water is crystal clear, and the sky is a vibrant blue. In the background, there are rolling hills and a few boats on the water. The overall atmosphere is bright and sunny.

Dairy consumption and 10-y total and cardiovascular mortality: a prospective cohort study in the Netherlands¹⁻³

R Alexandra Goldbohm, Astrid MJ Chorus, Francisca Galindo Garre, Leo J Schouten, and Piet A van den Brandt

Design: The NLCS was initiated in 120,852 men and women aged 55–69 y at baseline in 1986. After 10 y of follow-up, 16,136 subjects with complete dietary information had died. Twenty-nine per- cent (men) and 22% (women) of these deaths were due to IHD or stroke. The validated 150-item food-frequency questionnaire provided detailed information on dairy products.

In conclusion, given the postulated risk-enhancing effects of dairy fat and the protective effects of low-fat dairy products, the role of dairy consumption in mortality generally appears to be neutral, particularly in men.

Milk and dairy consumption and incidence of cardiovascular diseases and all-cause mortality: dose-response meta-analysis of prospective cohort studies¹⁻³

Sabita S Soedamah-Muthu, Eric L Ding, Wael K Al-Delaimy, Frank B Hu, Marielle F Engberink, Walter C Willett, and Johanna M Geleijnse

Am J Clin Nutr 2011;93:158–71.

Overall, this study showed no association between milk and total mortality, but modest inverse associations with CVD. Milk and dairy products cannot be recommended to benefit CVD health outcomes on the basis of this dose-response meta-analysis. Intake of milk and dairy products does not seem to be harmful, but whether the association is truly inverse cannot be firmly concluded. Further studies are warranted to investigate the relation between consumption of dairy products and risk of CVD and to investigate different dairy components separately with sufficient follow-up to assess multiple health outcomes.
